

What is the output of the following code:

```
byte destinationVar;  
short sourceVar = 281;  
destinationVar = (byte)sourceVar;  
Console.WriteLine($"sourceVar val: {sourceVar}");  
Console.WriteLine($"destinationVar val: {destinationVar}");
```

```
    sourceVar val: 281  
Sol: destinationVar val: 25
```

```
281 = 100011001  
25  = 000011001  
255 = 011111111
```

Two keywords exist for setting what is called the *overflow checking context* for an expression:
checked and unchecked.

```
byte destinationVar;  
short sourceVar = 281;  
destinationVar = checked((byte)sourceVar);  
Console.WriteLine($"sourceVar val: {sourceVar}");  
Console.WriteLine($"destinationVar val: {destinationVar}");
```
